Introduction

Sol-gels are the precursors to both xerogels and aerogels, and have had increasing interest due to their potential applications. Research has been done on the gels and their potential use in controlled release drug delivery systems,1 as potential gas sensors,2 as well as in air purification, fire retardation, and sound insulation in buildings.3

Surface-enhanced Raman spectroscopy (SERS) is a well-established method for selective molecular identification and has been used in electrochemical, biological and chemical sensing.4 It has even been looked at as a potential process for monitoring of chemical and/or biological weapons.5

4-Mercaptobenzoic acid (4-MBA, Figure 1) is a well-studied, pH sensitive, active SERS molecule. This makes it useful as a target molecule in the attempt to test base-catalyzed silica sol-gels as substrates for SERS and to determine how the 4-MBA reacts to different pH environments in the substrates.

Methods

The following chemicals were purchased from Sigma Aldrich (Milwaukee, WI): tetramethyl orthosilicate (TMOS, 98%), 4-mercaptopbenzoic acid (4-MBA, 99%), sodium citrate (98%), and silver nitrate (99.8%).

Ag Colloid preparation: All glassware was cleaned with Aqua Regia (3:1, conc. HCl:conc. HNO₃), then rinsed with DI water. AgNO₃ (50 mL, 1mM) and DI water (25 mL) were brought to boil with stirring. Sodium citrate (7.0 mL, 1%) was added and the solution boiled (30 min). Upon completion, the solution was cooled to room temperature and stored in the refrigerator.

Base-Catalyzed Sol-gel synthesis: Methanol (5.52 mL), tetramethyl orthosilicate (1.92 mL), DI water (0.762 mL), and ammonium hydroxide (0.0052 mL, 30%) were combined and stirred for 10 min. Ag colloid (3.75 mL) was added, stirred for 10 min more before adding 4-mercaptopbenzoic acid (3.75 mL). The solution was stirred for 5 min before pouring into plastic cuvettes to gel. Blank made by replacing 4-MBA with DI water.

Acid-Catalyzed Sol-gel synthesis: Tetramethyl orthosilicate (1.92 mL), methanol (1.13 mL), HCl (0.035 mL, 0.04 N), DI water (4.11 mL) and 4-MBA (3.75 mL, 2000 µM) combined and sonicated 10 min. Ag colloid and water were added with a combined volume of 3.75 mL, varying the amount of Ag, and solution sonicated 1 more minute.

Results

Figure 1: SERS of acid-catalyzed xerogels for select volumes of silver nanoparticles to a constant 4-MBA concentration (2000 µM)

Figure 2: SERS of base-catalyzed xerogels for select volumes of silver nanoparticles to a constant 4-MBA concentration (2000 µM)

Figure 3: SERS of base-catalyzed aerogels for varying concentrations of 4-MBA to a constant concentration of silver nanoparticle (3.75 mL). Ag colloid solution to 14.7072 mL sol-gel solution.

Figure 4: SERS of acid- and base-catalyzed aerogels for 1.875 mL of silver nanoparticle to a constant 4-MBA concentration (2000 µM)

Discussion

At all coverages of 4-MBA in the gels, there is no peak at 2580 cm⁻¹ (Fig. 1, 3, 5). This indicates the 4-MBA binds to the silver surface through the thiol group, which is consistent with earlier research.7 From Table 1 and all 5 figures, we can see that in-plane ring vibrations are occurring. This indicates perpendicular orientation to the silver colloid. Tilting toward the silver surface may be caused by the interaction of COO- groups with the surface of the colloid. This is seen more at low concentrations and a more vertical orientation is expected to occur at higher concentrations.8 These results also coincide with the environments effect on the 4-MBA. In Figures 1 and 2, the prominent differences in the state of the 4-MBA based on the different pH environments can be seen. The acid-catalyzed aerogels lack the size of the COO- peak at 1374 cm⁻¹ that is seen in the base-catalyzed spectrum. This difference can’t be seen in the aerogel comparison in Figure 4, which shows no significant peak differences between the two procedures. Figure 4 does indicate the base-catalyzed reaction may provide better spectra due to the larger intensity and sharper spectra.

As seen in Figure 5, the 4-MBA peaks start to increase at 319. µM, with small signs at 1.7 and 12.7 µM. In conclusion, the acid- and base-catalyzed silica sol-gels, aerogels, and xerogels seem to be successful SERS substrates. The 4-MBA seems to be more vertically oriented in the gels with slight tilting depending on the concentration, and the peaks also seem to adjust with the pH.

Future Studies

Future investigations will look into potential acid-base sensor applications for the sol-gels, aerogels and aerogels.
